Applications

In practice

# Genetic markers

## Genetic markers:

- genetically inherited traits which vary between individuals
- items of a nucleic or proteic sequence which vary between individuals

## Technically:

- a marker is a variable with different states; one marker = one *locus* (pl. *loci*)
- states are called *alleles*
- one individual can possess several alleles for one locus

# Genetic markers

## Genetic markers:

- genetically inherited traits which vary between individuals
- items of a nucleic or proteic sequence which vary between individuals

## Technically:

- a marker is a variable with different states; one marker = one *locus* (pl. *loci*)
- states are called *alleles*
- one individual can possess several alleles for one locus

## Microsatellites

*microsatellites* are chunks of DNA formed by the repetition of a short sequence of nucleotides. Variability lies in the number of repetitions.

Example:

Individual 1: TTATTATTATTA / TTATTA

Individual 2: TTATTATTA / TTATTATTA

In practice, recoded as:

Individual 1: 4/2

Individual 2: 3/3

Microsatellites can be highly variable (lots of alleles).

# Single Nucleotide Polymorphism (SNP)

*SNPs* are nucleotides which vary in a set of aligned DNA sequences.

Example:

Individual 1: ATG**G**GTATC**T**G

Individual 2: ATG**C**GTATC**A**G

SNPs are often binary (two alleles), but analysed in large numbers (thousands).

## Data: general aspect

- in practice, genetic markers form tables of relative frequencies of alleles.
- data can be aggregated by groups

## Data: general aspect

- in practice, genetic markers form tables of relative frequencies of alleles.
- data can be aggregated by groups

## Data: general aspect

- in practice, genetic markers form tables of relative frequencies of alleles.
- data can be aggregated by groups

In general, we analyse allele frequencies of individuals or groups (*biological entities*).

# Data coding

Raw data:

	locus1	locus2
1	80/80	30/30
2	50/55	30/30
3	80/50	29/30
4	50/50	30/30
5	50/50	29/29

Recoded data:

	locus1.50	locus1.55	locus1.80	locus2.29	locus2.30
1	0.0	0.0	1.0	0.0	1.0
2	0.5	0.5	0.0	0.0	1.0
3	0.5	0.0	0.5	0.5	0.5
4	1.0	0.0	0.0	0.0	1.0
5	1.0	0.0	0.0	1.0	0.0

# Data coding

# Outline

## Which data and which questions?

Genetic data

Objectives

## Methodological approaches: an overview

Different approaches

Model-based approaches

Exploratory approaches

## Multivariate analysis

Rationale

Applications

In practice

## Identifying genetic groups

Genetic clusters can indicate populations, i.e. groups of random mating individuals.

## Identifying genetic groups

Genetic clusters can indicate populations, i.e. groups of random mating individuals.

## Correlating genotype and phenotype

Correlations between alleles and phenotypic features can indicate the genetic determinism of a trait.

## Reconstructing evolutionary history

Genetic distances can be used to infer the evolutionary history of a set of taxa.

## Inferring migration routes

Examination of genetic diversity can be used to infer migration routes.

## Many possible applications

- different types of genetic markers (microsatellites, SNPs, etc.)
- wide range of questions (identifying populations, reconstructing evolutionary history and migrations, etc.)

→ a large variety of methods.

## Multivariate analysis

Rationale

Applications

In practice

## Bayesian clustering

- formulate a model of the data  $y$  with parameters  $\theta$  (e.g. group membership) and prior distribution ( $p(\theta)$ )
- formulate a likelihood  $p(y|\theta)$  for a given set of parameters  $\theta$
- obtain the posterior distribution of the parameters  $p(\theta|y)$

The posterior distribution is determined as (Bayes' formula):

$$p(\theta|y) = \frac{p(y|\theta)p(\theta)}{p(y)}$$

or in practice, since  $p(y)$  is often unknown:

$$p(\theta|y) \propto p(y|\theta)p(\theta)$$

In other words:

param. given data  $\propto$  data given param.  $\times$  prior param.

## Bayesian clustering

- formulate a model of the data  $y$  with parameters  $\theta$  (e.g. group membership) and prior distribution ( $p(\theta)$ )
- formulate a likelihood  $p(y|\theta)$  for a given set of parameters  $\theta$
- obtain the posterior distribution of the parameters  $p(\theta|y)$

The posterior distribution is determined as (Bayes' formula):

$$p(\theta|y) = \frac{p(y|\theta)p(\theta)}{p(y)}$$

or in practice, since  $p(y)$  is often unknown:

$$p(\theta|y) \propto p(y|\theta)p(\theta)$$

In other words:

param. given data  $\propto$  data given param.  $\times$  prior param.

## Bayesian clustering

- formulate a model of the data  $y$  with parameters  $\theta$  (e.g. group membership) and prior distribution ( $p(\theta)$ )
- formulate a likelihood  $p(y|\theta)$  for a given set of parameters  $\theta$
- obtain the posterior distribution of the parameters  $p(\theta|y)$

The posterior distribution is determined as (Bayes' formula):

$$p(\theta|y) = \frac{p(y|\theta)p(\theta)}{p(y)}$$

or in practice, since  $p(y)$  is often unknown:

$$p(\theta|y) \propto p(y|\theta)p(\theta)$$

In other words:

param. given data  $\propto$  data given param.  $\times$  prior param.

## Bayesian clustering

- formulate a model of the data  $y$  with parameters  $\theta$  (e.g. group membership) and prior distribution ( $p(\theta)$ )
- formulate a likelihood  $p(y|\theta)$  for a given set of parameters  $\theta$
- obtain the posterior distribution of the parameters  $p(\theta|y)$

The posterior distribution is determined as (Bayes' formula):

$$p(\theta|y) = \frac{p(y|\theta)p(\theta)}{p(y)}$$

or in practice, since  $p(y)$  is often unknown:

$$p(\theta|y) \propto p(y|\theta)p(\theta)$$

In other words:

param. given data  $\propto$  data given param.  $\times$  prior param.

# Bayesian clustering

$$p(\theta|y) \propto p(y|\theta)p(\theta)$$

## Bayesian clustering

$$p(\theta|y) \propto p(y|\theta)p(\theta)$$

In practice, we sample from  $p(\theta|y)$  using Markov Chain Monte Carlo (MCMC) algorithms.

MCMC (at step  $t$ ):

1. simulate candidate values of the parameters  $\theta^t$
2. compute  $p(\theta^t|y)$
3. accept/reject  $\theta^t$  as a part of the posterior distribution based on the comparison of  $p(\theta^t|y)$  with previous step  $p(\theta^{t-1}|y)$
4. increase  $t$ , return to step 1

## Bayesian clustering

$$p(\theta|y) \propto p(y|\theta)p(\theta)$$

In practice, we sample from  $p(\theta|y)$  using Markov Chain Monte Carlo (MCMC) algorithms.

MCMC (at step  $t$ ):

1. simulate candidate values of the parameters  $\theta^t$
2. compute  $p(\theta^t|y)$
3. accept/reject  $\theta^t$  as a part of the posterior distribution based on the comparison of  $p(\theta^t|y)$  with previous step  $p(\theta^{t-1}|y)$
4. increase  $t$ , return to step 1

## Bayesian clustering: example

STRUCTURE analysis of Human data (377 microsatellites, 52 populations, 1056 individuals)

(Rosenberg et al 2002, *Science*)

# Phylogenetic reconstruction

Reconstruct a tree (tips=observations, nodes=inferred ancestors) which fulfills a given criterion.

## Different approaches:

- maximum *parsimony*: minimal number of changes between ancestors and descendents
- maximum *likelihood*: find  $\theta$  so that  $p(y|\theta)$  is maximum
- Bayesian approach: estimate  $p(\theta|y)$  based on Bayes' formula

# Phylogenetic reconstruction

Reconstruct a tree (tips=observations, nodes=inferred ancestors) which fulfills a given criterion.

## Different approaches:

- maximum *parsimony*: minimal number of changes between ancestors and descendents
- maximum *likelihood*: find  $\theta$  so that  $p(y|\theta)$  is maximum
- Bayesian approach: estimate  $p(\theta|y)$  based on Bayes' formula

# Phylogenetic reconstruction

Different approaches

Model-based approaches

Exploratory approaches

## Multivariate analysis

Rationale

Applications

In practice

## Distance-based trees

Often confused with phylogenies. In fact, these trees do not generally try to reconstruct the evolutionary history. They just represent genetic distances.

### General approach:

- compute a genetic distance between biological entities (e.g. individuals, populations, species)
- use hierarchical clustering algorithm on the genetic distance matrix
- use bootstrap to evaluate uncertainties in the bifurcations

## Distance-based trees

Often confused with phylogenies. In fact, these trees do not generally try to reconstruct the evolutionary history. They just represent genetic distances.

### General approach:

### General approach:

- compute a genetic distance between biological entities (e.g. individuals, populations, species)
- use hierarchical clustering algorithm on the genetic distance matrix
- use bootstrap to evaluate uncertainties in the bifurcations

## Distance-based trees: example

Unexpected biodiversity in the giraffe based on 14 microsatellites (allele-sharing distance + NJ).

(Brown et al. 2007, *BMC Biology*)

## Multivariate analysis

Represent genetic distances using a small number of *synthetic variables*.

How do they work?

What can they be used for?

What software to use?

...

## Recall: the data

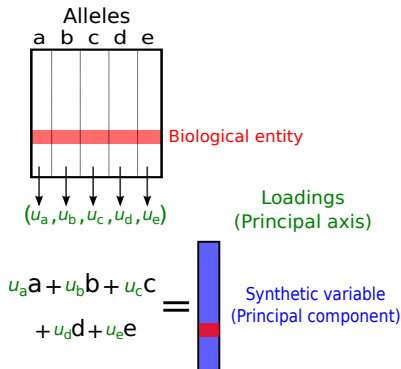

## Geometric approach of the data

Data form a cloud of points in a multivariate space:

# Rationale of multivariate analyses

Finding the directions showing most information.

## Outputs of multivariate analyses

- principal components: summarize genetic diversity
- principal axes: allele contributions

## Multivariate analyses: computations

### Notations:

- $n$ : number of entities
- $p$ : number of alleles
- $\mathbf{X} \in \mathbb{R}^{n \times p}$ : transformed data matrix (e.g. centred/scaled allele frequencies)
- $\mathbf{D}$ : a metric in  $\mathbb{R}^n$  (weights for entities)
- $\mathbf{u}$ : a normed vector of  $\mathbb{R}^p$ , i.e.  $\|\mathbf{u}\|^2 = 1$  (loadings)
- $\mathbf{Xu} \in \mathbb{R}^n$ : a linear combination of alleles

*Problem:* find  $\mathbf{u}$  so that  $\mathbf{Xu}$  are most scattered  
 $\Leftrightarrow \mathbf{u}$  so that  $\|\mathbf{Xu}\|_{\mathbf{D}}^2$  is maximum.

## Multivariate analyses: computations

$\Leftrightarrow \mathbf{u}$  so that  $\|\mathbf{Xu}\|_{\mathbf{D}}^2$  is maximum.

## Multivariate analyses: computations

*Problem:*  $\mathbf{u}$  so that  $\|\mathbf{Xu}\|_{\mathbf{D}}^2$  is maximum.

*Solution:*

- take  $\mathbf{u}_1$  the first eigenvector of  $\mathbf{X}^T \mathbf{D} \mathbf{X}$  associated to the eigenvalue  $\lambda_1$ ; then  $\|\mathbf{Xu}_1\|_{\mathbf{D}}^2$  is maximum and equates  $\lambda_1$
- with the constraint  $\mathbf{u}_1 \perp \mathbf{u}_2$ ,  $\|\mathbf{Xu}_2\|_{\mathbf{D}}^2$  is maximum and equates  $\lambda_2$
- further axes  $\mathbf{u}_i$  maximise  $\|\mathbf{Xu}_i\|_{\mathbf{D}}^2$  and are orthogonal to previous axes (i.e.,  $\mathbf{u}_i \perp \mathbf{u}_j \ \forall \ j < i$ )

## Multivariate analyses: computations
